

EP0376331

Publication Title:

Slow release drug delivery granules and process for production thereof.

Abstract:

Abstract of EP0376331

Slow release drug delivery granules comprising porous granules of a calcium phosphate compound having a ratio of Ca to P of 1.3 to 1.8, a porosity of 0.1 to 70%, a specific surface area of 0.1 to 50 m²/g and a pore size of 1nm to 10 μ m, fired at a temperature of 200 to 1400 DEG C, and a drug component impregnated in pores of the granules, and a process for producing the same. The drug delivery granules of the present invention has a controllable and good prolonged effect of the drug release and a good imaging property to an X-ray or ultrasonic wave, and therefore can be advantageously utilized in the field of a chemotherapy.

54 Slow release drug delivery granules and process for production thereof.

EP 0 376 331 A2
 57 Slow release drug delivery granules comprising porous granules of a calcium phosphate compound having a ratio of Ca to P of 1.3 to 1.8, a porosity of 0.1 to 70%, a specific surface area of 0.1 to 50 m²/g and a pore size of 1nm to 10 μm, fired at a temperature of 200 to 1400 °C, and a drug component impregnated in pores of the granules, and a process for producing the same. The drug delivery granules of the present invention has a controllable and good prolonged effect of the drug release and a good imaging property to an X-ray or ultrasonic wave, and therefore can be advantageously utilized in the field of a chemotherapy.

FIG. 1

SLOW RELEASE DRUG DELIVERY GRANULES AND PROCESS FOR PRODUCTION THEREOF

BACKGROUND OF THE INVENTION

5 Field of the Invention

The present invention relates to a drug delivery granule, more particularly, a drug delivery granule capable of slowly releasing impregnated drug components therefrom. Since the drug delivery granule of the present invention has a controllable and good prolonged effect of the drug release and a good imaging
10 property to an X-ray or ultrasonic wave, it can be advantageously used in the field of a chemotherapy, for example. The present invention also relates to a process for the production of such a drug delivery granule.

15 Description of the Prior Art

In the field of a chemotherapy, there have been desired to provide slow release drugs which can exhibit a prolonged effect or action thereof for the longest possible period. In particular, since a transvascular chemotherapy has been recently developed and is effectively used to treat a hepatoma or similar tumors, the researchers are studying slow release drugs which are effective for the transvascular chemotherapy.

20 For use in the chemotherapy, several types of slow release drugs are well-known. Typical examples of the prior art slow release drugs include a sponge preparation comprising sponge-like particles of the substance originated from an organism such as gelatin or the like and a drug component impregnated in the particles, or a suspension of drug particles in a fatty oil such as LIPIODOL (trade name of an ethyl ester of iodized poppy seed oil fatty acid; commercially available from Kodama K.K.). However, these drug
25 particles suffer from many drawbacks such that a drug is not concentrated on a site to be treated because of an unevenness of the particles size, that a prolongation of the effect of the drug is not satisfactory because the drug is easily diffused in and absorbed by a living body, and that, after application, the drug can not be traced because it has no imaging property to the X-ray or ultrasonic wave.

Further, Japanese Unexamined Patent Publication (Kokai) No. 60-106459 discloses that a calcium
30 phosphate-based filler containing a antibiotic substance can be produced by coating beads of a combustible substance with calcium phosphate, piercing the coated beads to open small holes therein, firing the beads to remove the combustible substance and filling the obtained hollow beads with the antibiotic substance through the hole of the bead wall. After filling of the antibiotic substance, the hole is closed or sealed to produce an antibiotic substance-containing filler. However, this production method is not suited for
35 producing small size fillers, because it is essential to open a small hole in the bead wall. Only relatively larger fillers having a diameter of 2 to 40mm can be produced. In addition, it needs troublesome operations such as filling of the antibiotic substance or sealing of the holes.

40 Summary of the Invention

Therefore, an object of the present invention is to provide slow release drug delivery granules having a good imaging property to the X-ray or ultrasonic wave, a prolonged effect of which granules can be controlled upon suitable selection of the porosity, specific surface area, pore size or the like of the porous
45 granules used.

Another object of the present invention is to provide a process of easily producing the slow release drug delivery granules.

According to the present invention, these objects can be accomplished by porous granules of a calcium phosphate compound having a ratio of Ca to P (Ca/P ratio) of 1.3 to 1.8, a porosity of 0.1 to 70 %, a
50 specific surface area of 0.1 to 50 m²/g and a pore size of 1nm to 10μm, fired at a temperature of 200 to 1400 °C. A drug or medicine is contained in pores of the granules.

Further, according to the present invention, the slow release drug delivery granules can be produced by impregnating the above-described porous granules of a calcium phosphate compound with a drug component and drying the thus impregnated granules.

Brief Explanation of the Drawings

The figures are graphs showing the results of measurements made in the working examples, in which:

Fig. 1 is a graph showing a change of a percentage of residual ADRIACIN (ADR) in the liver with
5 time,

Fig. 2 is a graph showing a change of a serum GOT level with time, and

Fig. 3 is a graph showing a change of a serum GPT level with time.

Fig. 4 is a graph showing a change of a light transmittance of a solution of a dyestuff released from
the granules in a dialysis tube with time.

10

Description of the Preferred Embodiments

In the practice of the present invention, the calcium phosphate compound used as a starting material of
15 the granules is not restricted, provided that it has a Ca/P ratio of 1.3 to 1.8. A Ca/P ratio of 1.35 to 1.75 is
preferable and a Ca/P ratio of 1.4 to 1.7 is more preferably. Typical examples of the calcium phosphate
compound useful in the invention include α - or β -tricalcium phosphate, tetracalcium phosphate, different
types of apatites such as hydroxyapatite or fluorinated apatite, and the like. These calcium phosphate
compounds may be used separately or in combination to form the granules. Porous granules used in the
20 present invention can be produced in accordance with any conventional method well-known in itself, such
as the method in which a foaming agent such as hydrogen peroxide is used to form pores in the granules,
or the method in which the calcium phosphate compound is mixed with a particulate substance capable of
being dissipated upon heating and the mixture is granulated and then heated to form the porous granules.

The porous granules used in the present invention are those fired at a temperature of 200 to 1400 °C,
25 preferably 500 to 1300 °C, more preferably 700 to 1200 °C. The firing at the temperature of less than
200 °C should be avoided, because the resulting granules have a less bonding strength and therefore can
be destroyed in a physiological saline or blood. The destruction of the granules means that the granules
can not be practically used in the chemotherapy. On the other hand, the firing temperature over 1400 °C
should be also avoided, because it causes decomposition of the calcium phosphate compound such as
30 hydroxyapatite.

Further, it is essential to the porous granules used in the present invention that they have a porosity of
0.1 to 70%, preferably 1 to 60%, more preferably 10 to 50%. The porosity of less than 0.1% is not suitable
for practical uses because of an excessively reduced drug content, and that of more than 70% is
inappropriate because the granules are unusable due to a reduced strength thereof.

Furthermore, it is essential to the porous granules that they have a specific surface area of 0.1 to 50
35 m²/g, preferably 1 to 40 m²/g, more preferably 10 to 30 m²/g. The specific surface area of less than 0.1
m²/g is not suitable for practical uses because a content of the drug component is reduced as a result of an
excessively reduced surface area to be adhered with the drug component, while the specific surface area of
more than 50 m²/g is inappropriate because a strength of the granules is reduced to a level not enough to
40 be used.

Moreover, to obtain a satisfactory retention capability of the drug component, the porous granules used
in the present invention should preferably have a pore size of 1nm to 10 μ m, more preferably 10nm to 8 μ m
, most preferably 50nm to 5 μ m. The pore size out of the above range is not preferable, because the pore
size of less than 1nm does not ensure a permeation of the drug into pores of the granules, and that of more
45 than 10 μ m does not ensure a retention of the drug in the pores.

In addition, preferably, the porous granules have a granule size of 1 μ m to 10mm. When the granules
are used in the transcatheter vascular embolization, they have preferably a granule size of 5 to 1000 μ m,
because capillary blood vessels generally have a diameter of at least 5 μ m and catheters used to apply the
granules to a blood vessel generally have an inner diameter of about 1000 μ m. In practice, the granules
50 have more preferably a granule size of 5 to 500 μ m, since it is ideal that the granules are retained in a
vessel near to a tumor tissue to be treated. The granules have most preferably a granule size of 10 to
100 μ m. On the other hand, when the granules are used as a filler, the size of the granules may vary
depending upon the size of defects to be filled. The granule size of less than 1 μ m is not suitable for the
filler, because the granules tend to be diffused in a living body too rapidly and to be englobed by a
55 macrophage etc., while the granule size of more than 10mm is not preferable, because large gaps among
the granules filled in an osseous defect portion are made so that the ossification can hardly occur.
Therefore, the granules for use as fillers have more preferably a granule size of 5 μ m to 5mm, most
preferably 10 μ m to 4mm. The granule size of the granules and a distribution of the granule size can be

suitably controlled by using a pertinent granulation technology of ceramics, depending upon the desired results.

The porous granules of the present invention may have a hollow structure in which the drug component is contained. In this case, it is essential that the shells of the hollow granules have a thickness of 1/10 or more of the granule size. The hollow granules can be produced in accordance with any well-known methods, and preferably can be produced by forming a porous coating of the calcium phosphate compound around particles of a combustible substance and heating and removing the combustible substance in a process of the firing.

The slow release drug delivery granules according to the present invention can be produced by impregnating the above-described porous granules of the calcium phosphate compound with a drug component, and drying the impregnated granules.

The impregnation of the drug component can be carried out by using any conventional methods. For example, if the drug component used is a liquid, it may be used without dilution or may be used after diluted with a diluent. The porous granules of the calcium phosphate compound are immersed in a liquid drug component or a diluted solution thereof. If the drug component is a solid, the impregnation can be carried out by dissolving or suspending the drug component in a suitable solvent and immersing the granules in the solution or suspension. The concentration of the drug component in the diluted solution or the solution or suspension can be suitably selected depending upon a specific amount of the drug component to be impregnated into the granules, but generally, it is preferred to select the highest concentration of the drug component to ensure an impregnation of the drug component into the granules as high level as possible.

After the impregnation has completed, the thus obtained granules impregnated with the drug component are dried to obtain the slow release drug delivery granules of the present invention. Drying may be carried out by using any conventional methods, for example, a heating method or a freeze-drying method. Drying by a heating method may be carried out by heating the impregnated granules in a constant temperature dryer at a temperature of 100 °C or less. However, since some drugs may be deteriorated at a high temperature, the freeze-drying is preferable. Freeze-drying may be carried out by using any conventional methods well-known per se. For example, the drug component-impregnated granules may be freeze-dried by freezing the granules at a temperature of -70 °C or less and dehydrating a frozen product in a vacuum pan under a reduced pressure of 10^{-4} to 10^{-7} Torr.

In the slow release drug delivery granules according to the present invention, a slow release action thereof can be controlled by suitably selecting a porosity, specific surface area and pore size of the granules of the calcium phosphate compound.

In addition, if the slow release drug delivery granules are coated with a soluble, organic polymeric compound, it is possible to increase a slow release action of the drug component, while controlling a specific gravity of the granules. The control of the specific gravity of the granules is important because of the following reason:

In applications of the slow release drug delivery granules in a transvascular treatment, if the granules used has a high specific gravity, it will cause a clogging of the delivery tube with the granules and accordingly prevent a delivery of the drug to a desired site to be treated. Since the particles of the calcium phosphate compound per se have a higher specific gravity than that of water, they may be coated with a substance having a lower specific gravity as compared with that of the calcium phosphate compound used, to reduce a specific gravity of the resulting slow release drug delivery granules, thereby ensuring an easy and correct delivery of the drug to the desired site.

The organic polymeric compound used as the coating substance preferably has a solubility and no toxicity to the human body, because it is desired that the coated substance is gradually dissolved in a blood or humor. Usable and useful polymeric compounds include, for example, albumin, dextran, ethyl ester of iodized poppy seed oil fatty acid, gelatin, carboxymethylchitin, glycol chitin and the like.

Coating may be carried out in accordance with any conventional methods well-known per se in the art. Suitable coating methods include, for example, (1) mixing the dried granules with the above-described organic polymeric compound or a solution thereof; (2) spraying the granules with the organic polymeric compound or a solution thereof; (3) mixing the granules with the organic polymeric compound having a particle size of 1/10 or less of the size of the granules and, if desired, a binder and water, and then stirring the mixture at a high speed. A layer thickness of the resulting coating can be suitably determined depending upon a desired specific gravity of the granules, or a desired level of the slow release effect.

In the present invention, the drugs to be impregnated into the granules are not limited to specific drugs, and include different types of the drugs such as carcinostatics, antibiotics and the like. And, the application of the slow release drug delivery granules is also not limited to specific methods, and include, for example,

a local injection or application as an implantation tablet or a filler, in addition to the transvascular chemotherapy.

According to the present invention, slow release drug delivery granules can be easily produced, and the drug delivery granules can exhibit an excellent slow release effect of the drug, because porous granules
 5 can contain a drug component in pores thereof. Further, a slow release effect of the granules can be freely controlled, because a granule size, distribution of the granule size, porosity, specific surface area, pore size or the like of the granules can be also controlled, if desired. Furthermore, since the granules of the calcium phosphate compound are used, the drug delivery granules have no toxicity to a human body, have an excellent imaging property to an X-ray or ultrasonic wave, and can be easily traced after the application
 10 thereof. Furthermore, when the granules are coated with an organic polymeric compound, the coated granules can exhibit a more improved slow release effect, and also can be suitably applied to a vascular embolization treatment, because a specific gravity of the granules can be freely controlled.

Moreover, the slow release drug delivery granules of the present invention can be applied by using any conventional methods, because the impregnation can be made with different types of the drugs, depending
 15 upon the specific application method used. For example, the granules can be suitably applied to make a treatment wherein a dissipation of the granules is desired, if a calcium phosphate compound having a high solubility, for example, tricalcium phosphate ($\text{Ca/P} = 1.5$), is used, and also they can be applied as a filler for an osseous defect portion, if a calcium phosphate compound having a low solubility, for example, hydroxyapatite ($\text{Ca/P} = 1.67$), is used.

20 The present invention will be further described with regard to the working examples thereof, but it should be noted that these examples do not restrict the scope of the present invention.

Example 1:

25 Porous hydroxyapatite granules having a Ca/P ratio of 1.67, average granule size of $30\mu\text{m}$, porosity of 50%, average pore size of 90 nm and specific surface area of $23.0\text{ m}^2/\text{g}$, fired at a temperature of 700°C , were prepared. The hydroxyapatite granules (100mg) were mixed with an aqueous solution of 10mg of ADRIACIN (trade name for the carcinostatic, doxorubicin sulfate, commercially available from Kyowa Hakko
 30 K.K.; hereinafter referred to as ADR) in 2 ml of water, to obtain the ADRIACIN-impregnated granules. The thus obtained impregnated granules were freeze-dried at -70°C under a reduced pressure of 10^{-4} to 10^{-7} torr by using MODULYO (NISSAN-EDWARD VACUUM K.K.) and disintegrated. The obtained granules were suspended in a mixed solution of 1ml of the iodine-type contrast medium: CONRAY (trade name for the injection solution, sodium iothalamate, commercially available from Daiichi Seiyaku K.K.) and 1ml of
 35 LIPIODOL (trade name of an ethyl ester of iodized poppy seed oil fatty acid; commercially available from Kodama K.K.). The suspension of the granules in LIPIODOL (hereinafter referred to the suspension of the HAL granules) were thus produced.

Example 2:

40 Porous hydroxyapatite granules having a Ca/P ratio of 1.67, average granule size of $400\mu\text{m}$ (granule size range of 300 to $500\mu\text{m}$), porosity of 40%, average pore size of 80nm and specific surface area of $25\text{ m}^2/\text{g}$, fired at 700°C were impregnated with ADRIACIN, freeze-dried and disintegrated in a similar manner
 45 to Example 1 to obtain the granules impregnated with ADR.

100ml of a 10% aqueous solution of dextran were sprayed on 50g of the above obtained impregnated granules under stirring in a stirrer at 300rpm and then dried at room temperature to obtain the dextran-coated granules having a coated layer of a thickness of 20 to $100\mu\text{m}$ (in dry state).

50

Example 3:

5% aqueous solution of gelatin was prepared by dissolving gelatin in water at 70°C and cooling the obtained solution to room temperature. $100\mu\text{m}$ of the above obtained gelatin solution were sprayed on 50g
 55 of the ADR-impregnated granules produced in Example 2 under the same stirring conditions as Example 2 and then dried at room temperature to obtain the gelatin-coated granules having a coated layer of a thickness of 50 to $200\mu\text{m}$ (in dry state).

Example 4:

50g of distilled water were sprayed on a mixture of 100g of the ADR-impregnated granules produced in Example 2 and 100g of carboxymethylchitin (average particle size of 20 μ m) in a stirrer and, after stirring at a high speed of 5000rpm, dried at room temperature to obtain the carboxymethylchitin-coated granules having a coated layer of a thickness of 100 to 300 μ m (in dry state).

Example 5:

Porous tricalcium phosphate (TCP) granules having a Ca/P ratio of 1.5, average granule size of 20 μ m (granule size range of 10 to 30 μ m), porosity of 30%, average pore size of 500nm and specific surface area of 4.2 m²/g, fired at 1100 °C were impregnated with ADRIACIN, freeze-dried and disintegrated in a similar manner to Example 1 to obtain the ADR-impregnated granules.

A mixture of 50g of the above obtained granules and 100ml of 2% aqueous solution of glycol chitin was dried and disintegrated to obtain the glycol chitin-coated granules having a coated layer of a thickness of 10 to 100 μ m (in dry state).

Example 6:

Hydroxyapatite powder having a Ca/P ratio of 1.67 and average particle size of 0.8 μ m was mixed with spherical acryl beads having an average size of 50 μ m which serve as cores of granules in a stirrer and stirred under spraying of distilled water at a high speed of 5000rpm. The thus coated beads were fired at a temperature of 900 °C to obtain the hollow granules of hydroxyapatite having an average granule size of 90 μ m (granule size range of 60 to 120 μ m). These hollow granules have a porosity of 50%, average pore size of 200nm and specific surface area of 14.5m²/g. ADR-impregnated granules were prepared by using the above obtained hollow granules in a similar manner to Example 2.

100 ml of 5% aqueous solution of albumin were sprayed on 50g of the above obtained hollow granules under the same stirring conditions as Example 2 and then dried at room temperature to obtain the coated granules having a coated layer of a thickness of 10 to 100 μ m (in dry state).

Experimental Example 1:

Each 0.1 ml of the suspension of the HAL granules produced in Example 1 was injected, through a common hepatic artery thereof, into male Wistar rats of the body weight of about 200g. After the injection of the suspension of the HAL granules, the liver was extirpated from the rats at a predetermined interval of time (immediately after injection, 6 hours after, 24 hours after, and 48 hours after) to determine an ADR amount in the liver with a high performance liquid chromatography (HPLC method). Five rats were used for each group. The results of the ADR determination are shown in the following Table 1 and Plotted in Fig. 1. Note, the ADR amount is indicated as a level (%) of the residual ADR in the liver; "100%" means the residual ADR determined immediately after the injection.

Experimental Example 2:

This example is a comparative example.

For comparison, the procedure of Experimental Example 1 was repeated with the proviso that the suspension of the HAL granules were replaced with a mixture of 10 mg of ADR and 2ml of CONRAY (hereinafter referred to as ADR mixture) or a suspension of 10 mg of ADR in a mixture of 1 ml of LIPIODOL and 1 ml of CONRAY (hereinafter referred to as ALC). The results of the ADR determination are also shown in the following Table 1 and plotted in Fig. 1.

Table 1

| Test material | Residual ADR (%) | | |
|----------------------------|------------------|----------------|----------------|
| | after 6hr. | after 24hr. | after 48hr. |
| Suspension of HAL-Granules | 49.8 | 13.6 | 8.2 |
| ADR Mixture | 35.4 | 10.0 | 3.0 |
| ALC | 16.0 | 4.8 | 1.1 |

The results of Table 1 show that the suspension of the HAL granules exhibit the highest residual ADR in the liver, and after 6 hours from the injection, they can maintain a high residual ADR of 49.8%. This means that according to the present invention, a slow release effect of the drugs can be notably improved in comparison with the prior art methods.

Experimental Example 3:

This example is intended to explain a reduction of the hepatic dysfunction by using the suspension of the HAL granules according to the present invention. For comparison, the ADR mixture and ALC used in Experimental Example 2 were also used herein.

Each 0.1ml of the test material (the suspension of HAL granules, ADR mixture or ALC) was injected, through a common hepatic artery thereof, into male Wistar rats of the body weight of about 200g. Before the injection of the test material, the hepatic artery was ligated. After injection of the test material, a level of GOT (aspartate aminotransferase) or GPT (alanine aminotransferase) in the serum was determined at a predetermined interval of time (immediately after the injection, 6 hours after, 24 hours after, and 48 hours after), and the results were summarized in the following Table 2 and plotted in Figs. 2 and 3.

As a control, the above procedure was repeated without injection of the test material. The results are also shown in Table 2 and Figs. 2 and 3.

Table 2

| Test material | GOT* (unit) | GPT* (unit) |
|----------------------------|----------------|----------------|
| Suspension of HAL-Granules | 1270 | 700 |
| ADR Mixture | 420 | 80 |
| ALC | 2310 | 2090 |
| Control | 150 | 40 |

*maximum value

The results of Table 2 show that if the suspension of the HAL granules of the present invention are used, a hepatic dysfunction can be significantly reduced in comparison with the prior art method in which the ALC was used as the test material. It is considered that these satisfactory results could be obtained, because hydroxyapatite used as a granule material has a good biocompatibility and a size of the granules can be adjusted to an inner diameter of the blood vessel. The granules had a size which is the same with or is lightly larger than the inner diameter of the blood vessel.

Example 7:

50g of porous hydroxyapatite granules having a Ca/P ratio of 1.67, granule size of 300 to 500 μ m, porosity of 40%, average pore size of 80nm and specific surface area of 25 m²/g, fired at 700^oC (used in Example 2) were added into 50ml of the brown ink (a recorder ink, available from CHUGAI KASEI K.K.) to

impregnate with the dyestuff and dried in a constant temperature drier at 50°C to obtain the dyestuff-impregnated granules (hereinafter referred to as granules A).

The obtained impregnated granules were coated with dextran in a similar manner to Example 2 to produce the dextran-coated granules (hereinafter referred to as granules B).

5

Example 8:

50 g of the dyestuff-impregnated granules produced in Example 7 were coated with gelatin in a similar manner to Example 3 to obtain the gelatin-coated granules (hereinafter referred to as granules C).

10

Example 9:

100g of the dyestuff-impregnated granules produced in Example 7 were coated with carboxymethyl-chitin in a similar manner to Example 4 to obtain the carboxymethylchitin-coated granules (hereinafter referred to as granules D).

15

Example 10:

The dyestuff-impregnated granules were produced with use of porous tricalcium phosphate (TCP) granules used in Example 5 in a similar manner to Example 7. 50g of the obtained dyestuff-impregnated granules were coated with glycol chitin in a similar manner to Example 5 to obtain the glycol chitin-coated granules (hereinafter referred to as granules E).

20

Example 11:

The dyestuff-impregnated granules were produced with use of the hollow granules of hydroxyapatite obtained in Example 6 in a similar manner to Example 7 and coated with albumin in a similar manner to Example 6 to obtain the albumin-coated granules (hereinafter referred to as granules F).

30

Experimental Example 4:

Dialysis tubes (seamless cellulose tubing 8/32 available from VISKASE SALES) were filled with 1g of each of granules A to F produced in Examples 7 to 11 and, after ligating both ends of the tubes with threads, introduced into a beaker containing 200 ml of distilled water and then stirred with a stirrer. Amount of the ink released into the distilled water was determined 1 hour after, 3 hours after, 6 hours after, 12 hours after and 24 hours after.

40

The amount of the ink released from the granules was determined by removing the tubes filled with the granules after elapse of the predetermined time, evaporating water in the beaker, redissolving the ink in 10ml of distilled water to give an aqueous solution of the ink and determining the concentration of the ink in the aqueous solution by means of a spectrophotometer (UV-100-01 available from SHIMAZU SEISAKUSHO) as a light transmittance at a wave length of 620nm. A light transmittance of "100%" means that of distilled water.

45

For comparison, dialysis tubes were filled with the same dyestuff as described in Example 7 (1ml ; the amount considered to be impregnated in 1g of the granules)and, after ligating both ends of the tubes with threads, introduced into a beaker containing 200 ml of distilled water and then stirred with a stirrer. Amount of the ink released into the distilled water was determined in the same manner as above. This experiment is carried out to obtain a control.

50

The results of the determination were plotted in Fig. 4.

The results shown in Fig. 4 indicate that the impregnated porous calcium phosphate granules release slowly the dyestuff, the concentration of the dyestuff in water increases gradually and the light transmittance decreases gradually, namely they have effect of slow release of the drug. Furthermore, the granules coated with an organic polymeric compound show more improved slow release effect, while the rate of releasing the drug varied depending on the coating substance and the structure of granules.

55

In these examples, hydroxyapatite and tricalcium phosphate were used as the calcium phosphate compound. However, it should be noted that similar and satisfactory results can be obtained with other calcium phosphate compounds such as those described above.

5

Claims

1. Slow, release drug delivery granules comprising porous granules of a calcium phosphate compound having a ratio of Ca to P of 1.3 to 1.8, porosity of 0.1 to 70%, specific surface area of 0.1 to 50 m²/g and pore size of 1nm to 10μm, calcined at a temperature of 200 to 1400 °C, and a drug component impregnated in pores of the granules.
2. Granules according to claim 1, in which the granules have a size of 1μm to 10mm.
3. Granules according to claim 1, in which the granules have a hollow structure and an inner space thereof contains the drug component.
4. Granules according to anyone of claims 1 to 3, in which the granules have a coating consisting of a soluble organic polymeric compound applied on a surface thereof.
5. Granules according to claim 4, in which the organic polymeric compound is selected from the group consisting of albumin, dextran, ethyl ester of iodized poppy seed oil fatty acid, gelatin, carboxymethylchitin and glycol chitin.
6. A process for the production of a slow release drug delivery granules, which comprises the steps of: impregnating porous granules of a calcium phosphate compound having a ratio of Ca to P of 1.3 to 1.8, porosity of 0.1 to 70%, a specific surface area of 0.1 to 50 m²/g and a pore size of 1nm to 10μm, fired at a temperature of 200 to 1400 °C, with a drug component; and drying the thus obtained impregnated granules.
7. A process according to claim 6, in which the granules have a size of 1μm to 10mm.
8. A process according to claim 6 or 7, in which the granules are impregnated with the drug component by immersing the granules in a bath containing the drug component.
9. A process according to one of claims 6 to 8, in which the impregnated granules are freeze-dried by freezing the granules at a temperature of -70 °C or less, and dehydrating the frozen product under a reduced pressure of 10⁻⁴ to 10⁻⁷ Torr.
10. A process according to one of claims 6 to 9, in which beads of a combustible substance are coated with the porous calcium phosphate compound, and the coated beads are heated to burn the combustible substance off, thereby producing the granules having a hollow structure:
11. A process according to one of claims 6 to 10, which further comprises the step of coating the dried granules with a soluble, organic polymeric compound.
12. A process according to claim 11, in which the dried granules are mixed with the organic polymeric compound or an aqueous solution thereof to form a coating of the polymeric compound.
13. A process according to claim 11, in which the dried granules are spray-coated with the organic polymeric compound or an aqueous solution thereof to form a coating of the polymeric compound.
14. A process according to claim 11, in which the dried granules are mixed with the organic polymeric compound having a particle size of 1/10 or less of the size of the granules and optionally a binder and water, and the mixture is stirred at a high agitation speed to form a coating of the polymeric compound.
15. A process according to one of claims 11 to 14, in which the organic polymeric compound is selected from the group consisting of albumin, dextran, ethyl ester of iodized poppy seed oil fatty acid, gelatin, carboxymethylchitin and glycol chitin.
